NEXT STEPS

- Carrier testing should be considered for the diseases specified above for the patient's partner, as both parents must be carriers before a child is at high risk of developing the disease.
- Genetic counseling is recommended and patients may wish to discuss any positive results with blood relatives, as there is an increased chance that they are also carriers.

What Is Smith-Lemli-Opitz Syndrome?

Smith-Lemli-Opitz syndrome (SLOS) is an inherited condition in which the body's ability to make cholesterol is impaired due to deficiency of the 7-dehydrocholesterol reductase enzyme. It is caused by mutations in the *DHCR7* gene. Cholesterol is critical for the structure of cells and is necessary for the normal development of a baby. Because of this, babies with SLOS often have birth defects. Cholesterol also plays an important role in the production of hormones and digestive acids. In addition to low cholesterol levels, SLOS also causes toxic byproducts of cholesterol production to build up throughout the body, further disrupting growth and development. The severity and types of symptoms can vary from individual to individual.

In children with little or no ability to make cholesterol, symptoms are severe. Some common birth defects in babies with SLOS are an abnormally small head (microcephaly), cleft palate, heart defects, and abnormal genitalia in male infants. They often have difficulty feeding because they lack the sucking reflex and have weak muscle tone. Some have extra fingers or toes as well as fused second and third toes on both feet, which is typical of SLOS. Infants with the severe form of SLOS grow slowly, and most have moderate-to-severe intellectual and developmental disabilities. Severely affected infants may also have problems with their kidneys, which can be life-threatening.

Some children have a milder form of the condition in which the body can produce some cholesterol. Symptoms may include developmental delays, toe defects, slow growth, and short stature. These children generally learn to walk and talk and can acquire other skills, although most do not become independent adults. Aggression is common in adults with SLOS. Sensitivity to sunlight (photosensitivity) is common in people with SLOS.

How Common Is Smith-Lemli-Opitz Syndrome?

SLOS affects an estimated 1 in 20,000 to 1 in 60,000 people. This disease is more common in those of European ancestry, especially in people from Slovakia and the Czech Republic. SLOS syndrome is rare among people of African and Asian descent.

How Is Smith-Lemli-Opitz Syndrome Treated?

There is no cure for SLOS, but some symptoms can be addressed. The primary treatment is to supplement the patient's diet with large amounts of cholesterol, either in the form of purified cholesterol or in the form of food such as egg yolks and cream. This has been shown to improve symptoms.

Early intervention and therapy help with speech and physical disabilities. Medication may treat symptoms such as vomiting, constipation, and gastroesophageal reflux. Surgery can often repair birth defects. Orthotics can help muscle spasms and improve mobility. Additional symptoms are treated as they arise.

Because the condition can cause extreme sun sensitivity, people with SLOS should try to stay out of the sun for long periods of time and should always wear sunscreen, sunglasses, and appropriate clothing when they go outdoors.

What Is the Prognosis for a Person with Smith-Lemli-Opitz Syndrome?

Although serious internal malformations can lead to early death, many people with SLOS can have a normal lifespan with good nutrition and medical care. Intellectual and developmental disabilities typically prevent people with this disease from living independently.

Methods and Limitations

JANE MILLER [Foresight Carrier Screen]: Sequencing with copy number analysis, triplet repeat detection, spinal muscular atrophy, and analysis of homologous regions (DTS v3.2).

Sequencing with copy number analysis

High-throughput sequencing and read depth-based copy number analysis are used to analyze the listed exons, as well as selected intergenic and intronic regions, of the genes in the Conditions Tested section of the report. The region of interest (ROI) of the test comprises these regions, in addition to the 20 intronic bases flanking each exon. In a minority of cases where genomic features (e.g., long homopolymers) compromise calling fidelity, the affected intronic bases are not included in the ROI. The ROI is sequenced to high coverage and the sequences are compared to standards and references of normal variation (Genome Reference Consortium Human Build 37 (GRCh37)/hg19). More than 99% of all bases in the ROI are sequenced at greater than the minimum read depth. Mutations may not be detected in areas of lower sequence coverage. Small insertions and deletions may not be as accurately determined as single nucleotide variants. Genes that have closely related pseudogenes may be addressed by a different method. *CFTR* and *DMD* testing includes analysis for both large (exon-level) deletions and duplications with an average sensitivity of 99%, while other genes are only analyzed for large deletions with a sensitivity of >75%. However, the sensitivity may be higher for selected founder deletions. The breakpoints of copy number variants and exons affected are estimated from probe positions. Only exons known to be included in the copy number variant are provided in the name. In some cases, the copy number variant may be larger or smaller than indicated. If *GJB2* is tested, large upstream deletions involving the genes *GJB6* and/or *CRYL1* that affect the expression of *GJB2* are also analyzed. Mosaicism or somatic variants present at low levels may not be detected. If detected, these may not be reported.

Detection rates are determined by using literature to estimate the fraction of disease alleles, weighted by frequency, that the methodology is unable to detect. Detection rates only account for analytical sensitivity and certain variants that have been previously described in the literature may not be reported if there is insufficient evidence for pathogenicity. Detection rates do not account for the disease-specific rates of de novo mutations.

All variants that are a recognized cause of the disease will be reported. In addition, variants that have not previously been established as a recognized cause of disease may be identified. In these cases, only variants classified as "likely" pathogenic are reported. Likely pathogenic variants are described elsewhere in the report as "likely to have a negative impact on gene function". Likely pathogenic variants are evaluated and classified by assessing the nature of the variant and reviewing reports of allele frequencies in cases and controls, functional studies, variant annotation and effect prediction, and segregation studies. Exon level duplications are assumed to be in tandem and are classified according to their predicted effect on the reading frame. Benign variants, variants of uncertain significance, and variants not directly associated with the intended disease phenotype are not reported. Curation summaries of reported variants are available upon request.

Triplet repeat detection

PCR is used to size the CGG repeat in the 5' UTR of *FMR1* (NM_002024.4: c.1-131CGG[1_n]). PCR products generated from fluorescently labeled primers are detected by capillary electrophoresis. Reported sizes are accurate to +/- 1 repeat for normal/intermediate alleles and +/-2 repeats for premutation alleles. Alleles above 200 CGG repeats (full mutations), while identified, are not sized. Nearby mutations may interfere with detection of CGG repeat expansions. Deletion of the CGG repeat region and other similar *FMR1* mutations may not be detectable. Methylation is not analyzed. Small degrees of size mosaicism, including gonadal mosaicism, may not be detected as the test has been calibrated to yield results that are equivalent to the results from Southern blot.

Spinal muscular atrophy

Targeted copy number analysis is used to determine the copy number of exon 7 of the *SMN1* gene relative to other genes. Other mutations may interfere with this analysis. Some individuals with two copies of *SMN1* are carriers with two *SMN1* genes on one chromosome and a *SMN1* deletion on the other chromosome. This is more likely in individuals who have 2 copies of the *SMN1* gene and are positive for the g.27134T>G SNP, which affects the reported residual risk; Ashkenazi Jewish or Asian patients with this genotype have a high post-test likelihood of being carriers for SMA and are reported as carriers. The g.27134T>G SNP is only reported in individuals who have 2 copies of *SMN1*.

Analysis of homologous regions

A combination of high-throughput sequencing, read depth-based copy number analysis, and targeted genotyping is used to determine the number of functional gene copies and/or the presence of selected loss of function mutations in certain genes that have homology to other regions. The precise breakpoints of large deletions in these genes cannot be determined, but are estimated from copy number analysis. High numbers of pseudogene copies may interfere with this analysis.

If *CYP21A2* is tested, patients who have one or more additional copies of the *CYP21A2* gene and a loss of function mutation may not actually be a carrier of 21-hydroxylase-deficient congenital adrenal hyperplasia (CAH). Because the true incidence of non-classic CAH is unknown, the residual carrier and reproductive risk numbers on the report are only based on published incidences for classic CAH. However, the published prevalence of non-classic CAH is highest in individuals of Ashkenazi Jewish, Hispanic, Italian, and Yugoslav descent. Therefore, the residual and reproductive risks are likely an underestimate of overall chances for 21-hydroxylase-deficient CAH, especially in the aforementioned populations, as they do not account for non-classic CAH. Some individuals with two functional *CYP21A2* gene copies may be carriers, with two gene copies resulting from a duplication on one chromosome and a gene deletion on the other chromosome. This and other similar rare carrier states, where complementary changes exist between the chromosomes, may not be detected by the assay.

If *HBA1*/*HBA2* are tested, extensive sequence homology between these two genes can prevent certain variants from being localized to one gene over the other. In these instances, variant nomenclature will be provided for both genes. If follow up testing is indicated for patients with nomenclature provided for both genes, both *HBA1* and *HBA2* should be tested. Some individuals with four functional alpha globin gene copies may be carriers, with three gene copies resulting from triplication on one chromosome and a single gene deletion on the other chromosome. This and other similar rare carrier states, where complementary changes exist between the chromosomes, may not be detected by the assay.

Limitations

In an unknown number of cases, nearby genetic variants may interfere with mutation detection. Other possible sources of diagnostic error include sample mix-up, trace contamination, bone marrow transplantation, blood transfusions and technical errors. This test is designed to detect and report germline alterations. While somatic variants present at low levels may be detected, these may not be reported. If more than one variant is detected in a gene, additional studies may be necessary to determine if those variants lie on the same chromosome or different chromosomes. This test is not designed to detect sex chromosome copy number variations. If present, sex chromosome abnormalities may significantly reduce test sensitivity for X-linked conditions. Residual and reproductive risks provided assume a normal karyotype. Risks for individuals with abnormal karyotypes may be different. The test does not fully address all inherited forms of intellectual disability, birth defects and genetic disease. A family history of any of these conditions may warrant additional evaluation. Furthermore, not all mutations will be identified in the genes analyzed and additional testing may be beneficial for some patients. For example, individuals of African, Southeast Asian, and Mediterranean ancestry are at increased risk for being carriers for hemoglobinopathies, which can be identified by CBC and hemoglobin electrophoresis or HPLC (*ACOG Practice Bulletin No. 78. Obstet.Gynecol. 2007;109:229-37*).

This test was developed and its performance characteristics determined by Myriad Women's Health, Inc. It has not been cleared or approved by the US Food and Drug Administration (FDA). The FDA does not require this test to go through premarket review. This test is used for clinical purposes. It should not be regarded as investigational or for research. This laboratory is certified under the Clinical Laboratory Improvement Amendments of 1988 (CLIA) as qualified to perform high-complexity clinical testing. These results are adjunctive to the ordering physician's evaluation. CLIA Number: **#05D1102604**.

Risk Calculations

Below are the risk calculations for all conditions tested. Since negative results do not completely rule out the possibility of being a carrier, the **residual risk** represents the patient's post-test likelihood of being a carrier and the **reproductive risk** represents the likelihood the patient's future children could inherit each disease. These risks are inherent to all carrier screening tests, may vary by ethnicity, are predicated on a negative family history and are present even after a negative test result. Inaccurate reporting of ethnicity may cause errors in risk calculation. The reproductive risk presented is based on a hypothetical pairing with a partner of the same ethnic group.

†Indicates a positive result. See the full clinical report for interpretation and details.
